

Macros

new-handle (implicit creation of a new contact)

This means the definition of a new contact. If a contact with the provided email address exists in the JOKER-DATABASE, a new contact will be created. The reference for the created handle is following the format COME-*number*, e.g. COME-176268.

ATTENTION:

The name of the request field depends on the context. If you want to create a contact for the owner-contact, you have to replace the "." at the beginning of the fieldname with "owner-contact".

If you want to create a contact for the admin-contact, you have to replace the "." at the beginning of the fieldname with "admin-contact".

If you want to create a contact for the tech-contact, you have to replace the "." at the beginning of the fieldname with "tech-contact".

If you want to create a contact for the billing-contact, you have to replace the "." at the beginning of the fieldname with "billing-contact".

There is a new request field called **name** within the context definition. This field is mandatory if you do not provide the request field **username**. You have to provide the request field **name**, if **frame** and **frame** are not found. This is very important for the whos output. Everywhere a **field person** is shown. If you are using the request field **name**, the whos is showing the value for **name**, regardless the content of the request fields **frame** and **frame**. If you do not provide the request field **name** but you are providing the request fields **frame** and **frame**, the whos is showing the concatenation of these fields.

There is also a new request field called **address-3** within the contact definition. This field is not mandatory, it is simply the 2nd line of the address.

Macros

1	2	3
---	---	---

An existing contact `{[record] or {name: ''} (no int)}`

This means an existing contact handle in the JOKER-DATABASE.

Example:

owner contact handle: COME-170208
admin contact handle: COME-170209
tech contact handle: COME-170208
billing contact handle: COME-170208

In case you have entered a non-existing contact handle, the system will send you an errormail.

It is also possible to set a reference to a contact definition, which has been made earlier within the current request. To do so, please use the following syntax:

admin contact handle name as owner contact

tech contact handle name as admin contact

billing contact handle name as tech contact

The `{[name]}` macro always replaces the value for the specified contact handle with the email address of the maketarget. If the referenced contact has to be created with this request, it takes the result handle.

Keep in mind that for now requests the contact handles for `{[contact real url]} {[contact id]}` contacts are not allowed. If you are referencing to a virtual file `home@joker.com`, you will get an error.
